

ABSTRACT OF THE DISCLOSURE

A magnetic resonance apparatus for examinations having a local gradient coil unit (insert gradient coils) has a driven support mechanism (patient bed) with which the examination subject can be introduced into the examination space of the magnetic resonance apparatus, and a coupling device with which a gradient coil unit can be coupled to the patient bed and can be moved into the examination space by the driven patient bed. The gradient coil unit is positioned in the examination space by the patient bed and does not require its own drive.
